this may have been asked before, maybe not:

I own a motherboard (gigabyte brand) with the integrated "giga-raid" raid controller, which is really powered by the ITE8212 chip set. Now, the drivers provided by ITE, include binary drivers for a few distros, including Debian Woody, and they include source for both 2.4 and 2.6 kernels, however i have not been able to get the drivers to compile at all. I am running Debian sarge, kernel 2.6.8. the make file for the 2.6 driver is hard coded to look for the 2.6.1 kernel source , and i have changed it to reflect to my kernel, however i still cannot compile this driver. When trying to compile i get a huge amount of errors/warnings almost all about various variables being undefined.

My question is this: has anyone gotten this controller running on Sarge? if so how?
