No sd driver listed there? Strange... are there any subdirectories under scsi/drivers at all? If no sd, then at least the SATA driver for your harddisk should be there (don't recall its name from your lsmod output... something like sata\_sil?).

Hmm, and I suppose that's exactly what the sd driver is supposed to tell... that would also explain why your digital camera isn't working (uses the sd driver, too), while your mouse and hub are fine.

Funny that although the sd driver apparently isn't used by anything (no output to syslog; device not visible, let alone mountable), its module-"Used By"-refcount still is 2... if your current kernel supports module unloading, you could try

- detach stick
- "rmmod sd\_mod"
- attach stick, check if the module is loaded automatically
- if not, detach, insmod manually, attach
- check for differences in syslog and system behaviour

Hmm, wildly stabbing in the dark... ;)
