I know there's a tool that will let me run "make install" and then creates a .deb (or .rpm, or .tgz, or ..) of it so that I can remove the package cleanly later and take a nice .deb to install on other machines. I know this exists, I just can't remember the name of the tool :-(Anyone who knows what I'm talking about?
/M

checkinstall

Yes, that's what I meant. Unfortunately it's broken in Sid :-(I had to revert to fcheck to get some sort of control on installing VMWare Client.

Software is not manufactured, it is something you write and publish. Keep Europe free from software patents, we do not want censorship by patent law on written works.

They that can give up essential liberty to obtain a little temporary safety deserve neither liberty nor safety.
