I am currently using kubuntu and want to test the etch dist. My board is a K8M Neo-V from MSI. I downloaded the netinst iso. The install process fails to setup the mobo LAN card. I disabled the internal LAN and installed a Linksys card with same results. On both occasions I tried a manual configuration with the setting that work for the kubuntu install. The only diff is that I substitute the HD (mounted for easy change) for a test drive.

Ideas?
