i can't remember how, but i was able to send mail to any email address from redhat using "mail someone@xxxxxxxxxxx "  
how can i get this with debian ?

Do you mean something like this:

```
echo "this is a test." | mail -s "test" user@xxxxxxxxxxx
```

You need to have a mail transfer agent (MTA) configured and running, if this shall work. The default MTA with Debian is Exim.

Which version of Debian (stable/testing/unstable) are you running? Is Exim or another MTA (postfix) installed and configured on your system?

would not be ssmtp the simples choice for such an enviroment (if the OP does not want to use fetchmail of course, otherwise it will create a loop i belive)

it supports address rewriting, tls, smtp auth ... everything that is needed for a simple enviroment

yours  
Albert
