I don't know if it is the time of the night here or whether it's because I am a newbie, but I can't seem to sort this out in my head. I thought I should write this before I do some damage, as it usually pays to prevent problems before they happen :-)

I would like to install FrostWire <http://www.frostwire.com/> which relies on Sun Java. I googled and ended up with this HowTo that is quite recent: <http://www.debian-administration.org/articles/444> I edited my `/etc/apt/sources.list` as per instructions (though I use a mirror close to me) in the HowTo. I installed the "fakeroot" package as per instructions, but could not find "java-package" with Synaptic, so I googled and found it here: [http://ftp.se.debian.org/debian/pool/contrib/j/java-package/java-package\\_0.28\\_all.deb](http://ftp.se.debian.org/debian/pool/contrib/j/java-package/java-package_0.28_all.deb)

So far, so good???

The URL included in the HowTo for downloading the latest Sun JDK seems to be out of date, but I found this URL:

<http://java.sun.com/j2se/1.5.0/system-configurations.html> scrolling down the table, I chose "Linux Intel IA32 JDK" which directs me here: <http://java.sun.com/j2se/1.5.0/install-linux.html> which provides me with all sorts of apparently useful instructions, but I can't find the #%! link to download the file(s). What am I missing???

Cheers,

Brian
