Running "lshw" on the box shows the motherboard as a Dell 0UW457, v. A03 with socket M2 and Nvidia GeForce 6150LE chipset. The BIOS version is about a year old (12/09/2006, v. 1.1.4), so it could probably use an upgrade.

Actually, if you have any tips on upgrading the BIOS from within Linux, give me a shout. Most of Dell's "solutions" for BIOS upgrade are convoluted or Windows-centric. I was playing around with the libsbios utilities the other day. Perhaps there is something in there to help...

Thanks,

Bogart

Ron,

Interesting: when the USB drive is on, the box stalls during POST. It is apparently some kind of deadlock, because when I power down the drive POST completes immediately.

What motherboard?
