yum install ccache should dtrt.

Mmm, reading the manpage isn't very concise about how to use it. I don't have a (G)CC env var set, but it looks like that method could be used (something like "CC=ccache; export CC" maybe) , so I have to ask can it, so my scripts, which do all this with a "make bzImage" or "make modules" commands apparently wouldn't need any changes?

after installing it, 'which cc' should point to ccache automatically rather than gcc, so you shouldn't have to do anything different than your usual build process. After building once, ccache -s should show some stats for the stuff in cache. A subsequent make should result in the 'cache hit' number being higher.

Dave
