I'd like to add that the same horrible problem happens when opening PHP files that happen to not be PHP files.  
I wonder why so much empathis is put on the file extension when Unix systems usually don't give a damn about them anyway \$ file filename and you know if it's ASCII or an MP3 or whatever.

Because KDE and now Gnome are trying to behave like Windoze, because the way to make a desktop popular seems to be to appease the lowest common denominator.

This warning is just as annoying for me as vista's "cancel or allow", it should be the responsibility of the program(text editor? audio player?) not to cause a security risk when trying to open a weird file.

Change your gnome preferences.
