I don't have an opinion in the matter, but I don't use Metacity and the last time I've tried I could track the windows positions between sessions, but it's a feature that I don't use.

So what do you use and can it save window state?

The only application I've in my session is GKrellM and it manages the position itself... ^\_\_^;

The problem has to do with multiple instances of the same program. So one xterm works fine. Gnome-terminal is actually a single instance with just multiple windows so that's probably why it works with multiple terminal windows.

Is there any scripting control over where Windows are positioned? Meaning, can I create a script file that I just run from the commandline once when I login such that I can start an xterm and then tell metacity to position it's window (identified by pid I suppose) on a particular desktop at a particular position?

Mike
