Just switched to 2.6.3 and I can report that this misbehavior is still there. Not quite as frequent as before (just a feeling). There seems to be another failure mode introduced now. At time it just freezes for about 1-3 seconds. I.e. The mouse just don't respond to anything. The crazy movements are the more common failure mode though.

Anyone else recognize this? I get the infamous "psmouse.c: Wheel Mouse at isa0060/serio1/input0 lost synchronization, throwing 1 bytes away." thing still...

suggestions are welcome...

/Anders
