After upgrading to 8.0, I get an error message telling me that /dev/null is not executable when I try to enter that with a chsh command. We use this when setting up ftp accounts for access to our web server. I can still go into /etc/passwd and manually enter that – and it works. So, if nothing else, I could just change the instructions for setting up ftp accounts.

But I'm wondering why the change?

All opinions stated are my own, and probably don't even vaguely resemble those of Navarro College. :)
