I've created an RPM and signed it, and I'm trying to distribute it to my various RHEL boxes. I've got a Yum repository going, and the boxes are communicating properly with it, but when I try to install the package, I get:

```
Downloading headers to solve dependencies...
#####
Downloading headers to solve dependencies...
#####
heartbeat-2.0.5-1.i386.rpm: ##### Done.
The package heartbeat-2.0.5-1 is not signed with a GPG signature.
Aborting...
Package heartbeat-2.0.5-1 does not have a GPG signature.
Aborting...
```

But I signed the package myself, and the following commands succeed:

```
$ rpm -Kv heartbeat-2.0.5-1.i386.rpm
heartbeat-2.0.5-1.i386.rpm:
Header V3 DSA signature: OK, key ID d42e7aef
Header SHA1 digest: OK (4ebcf1aaf7832fae00e9c78a3c09b812e379f935)
MD5 digest: OK (c15a01b644c5514ac9b73cff7d8f644)
V3 DSA signature: OK, key ID d42e7aef
$ rpm --checksig heartbeat-2.0.5-1.i386.rpm
heartbeat-2.0.5-1.i386.rpm: (sha1) dsa sha1 md5 gpg OK
```

Note particularly that, in the case of `--checksig`, it reports that the gpg signature is OK! I'm running fully updated copies of RHEL 4:

```
$ rpm -qv up2date
up2date-4.4.67-4
```

The only similar problems I've found on google were with packages that weren't, in fact, signed, but `rpm --checksig` and `-Kv` return very different text in those cases.

I've tried regenerating the Yum repository headers as well in case `up2date` was looking at those, but that didn't solve the problem.

"Package is not signed..."

"Package is not signed..."

Thoughts? Thanks!
