I have a system with an older Redhat 7.2 in house system.

The system locked up, and I was forced to cycle power to get it out of its locked-up state. The machine booted back up fine and no errors were detected as of any of the log files. However, it is failing to recognize basic key codes from the keyboard. left, right, up, down, F1...F12, PgUp, PgDn, etc. It will type letters fine, enter, and tab but that is it. This is on a KVM, I switched to other machines on this switch and the keyboard dose fine. I changed the keyboard out, but that didn't correct it either.

I'm looking for a way to perhaps go into libs or setting somewhere and reset or perhaps reload whatever takes care of the keyboard. Any idea were to start looking... Agin there is no cluse in the loggs files.

This sound more like a problem with your console than with the keyboard. Look to see if the /etc/termcap file has been corrupted or deleted.

Carl.
