I was running 3.x before that – got hacked when I wasn't looking one day. That's when I upgraded to 6.2, then 6.3 (as updates)...

I downloaded 8.?, but I decided that I had spent so much time learning ipchains & getting my firewall correct, that I didn't feel like reinvesting said time for learning iptables – just to stay modern. It's strictly a server, no apps running on it, only sendmail, apache, ssh, printserv, and timed. Decided there was no need for an update until the machine decides to die, and maybe not even then.

Wow! 6.3? I thought RHL went from 6.2 to 7.0!

I'm running 256M RAM with 6.3. All patches. Does what it needs to do.

Never been hacked.

Geez, my server is still at 6.3...

Yeah, well, I may upgrade to a box that a friend scored that was being

thrown out where he works. I can see that it's got more than 32M of RAM...

A few years ago, I set up the box that I use for a firewall/router, running RH9, as my printserver. Well, earlier this year, I had a hard

drive crash, and had to rebuild the box. Now I'm trying to set it up again for the same. I
must be dense, or going senile, but I have yet to figure it out. Do

I

- 1) use redhat-config-printer?
- 2) if so, do I tell it local printer, or Unix print server(lpd)?
- 3) if the former, how do I tell CUPS to use it, and advertise it to the other systems on my network, and to actually pass requests to it to be printed, rather than have them go to nowhere?
- 4) if the latter, do I tell it to use cups, or what?
