Hello SuSE people,

Running 9.2 -2.6 kernel. Last night I did a YOU update. It bumped me up to the .11 version of the kernel from the .10 version.

Tonight I went to do an apt-get update/upgrade. I received a message:
The following packages have unmet dependencies:

kernel-default-nongpl#2.6.8-24.10: Depends: kernel-default (= 2.6.8-24.10) but 2.6.8-24.11 is installed.

So I did a `uname -r` That showed the 2.6--.11 kernel.

So then I did an `rpm -qa`. That showed that I had one version of `kernel-default` and one version of `kernel-sources` (.11 version) and two versions of `kernel-source-nongpl`. the .10. and the .11 versions.

So then I went in and looked at `/var/lib/YaST2/you/mnt/i386/update/9.2/deltas & /rpms` (the deltas are what the patches are, right?) figuring I would just delete the old .10 versions and be on my merry way.

Wrong, to my surprise I found two versions, .5 (which I surmise is the original kernel from the install), and .10. No .11 !! Now I am really confused.

Where did YOU put .11 ?? And when it installs the `kernel-default` does it also install both of the sources? And if it does, why doesn't it overwrite/delete the old packages ??

Sooo, how do I `rpm -e` the `kernel-source-nongpl .10` package when there are two versions with the same name? Can I delete the old .5 & .10 rpm's and hope that the .11 packages are somewhere?? And, do I even need the `kernel-source-nongpl` file ?

Bob S.

PS Did an `rpm rebuilddb` just to be sure.
