Hi Mohsen

– What is the intended use of the PC? Is it a standalone workstation, does it serve other PC's? This will govern what you want to start/run.

– You can certainly go into the runlevel editor and disable what you don't want. You might of course have to do some research.

– Is the machine resource limited? If you are low on RAM for example that will slow things.

– There are other ways to speed up the boot process as well, like disabling new hardware detection. Have a browse around on that topic. I recall someone experimenting with a distro and getting it to boot in maybe 1/3 the time.

I get around the start delay by not turning the PC off!

Cheers Bob
